∃ ► < ∃ ►</p>

The Drainage Network with Branching (DNB) will depend of two family of variables:

- (ω(z))<sub>z∈Z<sup>2</sup></sub>: A family of independent Bernoulli random variables with parameter p ∈ (0, 1).
- (θ(z))<sub>z∈Z<sup>2</sup></sub>: A family of independent and identically distributed random variables on {−1, 0, 1} that depends on a parameter ε ∈ (0, 1) and have the following probability function:

$$P(\theta(z)=0)=\epsilon,$$
  $P(\theta(z)=-1)=P(\theta(z)=1)=rac{1-\epsilon}{2}.$ 

 $\mathcal{X}_{\epsilon}$  will denote the DNB with branching parameter  $\epsilon$ .

$$\begin{split} \mathcal{X}_{\epsilon_n}^n &= \{ (\frac{z_1}{n}, \frac{z_2}{n^2}) \in \mathbb{R}^2 : (z_1, z_2) \in \mathcal{X}_{\epsilon} \} \text{ will denote the diffusively rescaled DNB.} \\ W_n^l &\subset \mathcal{X}^n \text{ will be the subset of the l-paths.} \end{split}$$

 $W_n^r \subset \mathcal{X}^n$  will be the subset of the r-paths.

◆□▶ ◆□▶ ◆□▶ ◆□▶ □ - つくつ

Our main objective is to describe the asymptotic behavior of the diffusively rescaled DNB when  $\epsilon_n = b n^{-\alpha}$  for different values of  $\alpha > 0$ , where b is a positive constant.

くロ と く 同 と く ヨ と 一

Our main objective is to describe the asymptotic behavior of the diffusively rescaled DNB when  $\epsilon_n = b n^{-\alpha}$  for different values of  $\alpha > 0$ , where b is a positive constant.

If we have  $\alpha \in [0, 1)$ , then  $\mathcal{X}_{\epsilon_n}^n$  does not converge in distribution under diffusive scaling. In this case,  $n \epsilon_n$  diverges to infinity when  $n \to \infty$ , which means that the lattice  $\mathbb{Z}^2$  is compressed faster than the reduction of the branching probability.

→ ∃ → < ∃ →</p>

Intuitively, the Brownian Web is a collection of coalescing Brownian motions, starting from every point in space-time plane  $\mathbb{R}^2$ .

[Fontes, Isopi, Newman and Ravishankar] Brownian Web

There exists an  $(\mathcal{H}, \mathcal{B}_{\mathcal{H}})$ -valued random variable  $\mathcal{W}$ , called standard Brownian Web, whose distribution is uniquely determined by the following properties:

(a) For each deterministic  $z \in \mathbb{R}^2$ , almost surely there is a unique path  $\pi_z \in \mathcal{W}(z)$ ;

(b) For any finite deterministic set of points  $z_1, \ldots, z_k \in \mathbb{R}^2$ , the collection  $(\pi_{z_1}, \ldots, \pi_{z_k})$  is distributed as coalescing (standard) Brownian motions;

(c) For any deterministic countable dense subset  $D \subset \mathbb{R}^2$ , almost surely, W is the closure of  $\{\pi_z : z \in D\}$  in  $(\Pi, d)$ .

イロト イポト イヨト イヨト 三日

The Brownian Web  $\mathcal{W}$  has a dual process  $\widehat{\mathcal{W}}$ , which is called the *dual Brownian Web*.  $\widehat{\mathcal{W}}$  is a collection of coalescing paths running backward in time, which is uniquely determined by the restriction that these paths cannot cross any path from  $\mathcal{W}$ .

The previous characterization can be extended to allow the Brownian paths to have a fixed diffusion coefficient  $\lambda^2 \neq 1$  and a drift  $b \neq 0$ . The only difference is in property (b), where the coalescing Brownian motions may have a diffusion coefficient distinct from one and a non-zero drift. We denote by  $W_{\lambda,b}$  the Brownian Web with diffusion coefficient  $\lambda^2 > 0$  and drift  $b \in \mathbb{R}$ , We also denote  $W_{\lambda,b} = W_{\lambda}$  if b = 0.

The Brownian Net generalizes the Brownian Web by allowing paths to branch and was described by Rongfeng Sun and J. M. Swart. We will denote by  $\mathcal{N}_b$  the Brownian Net with branching parameter *b*.

< ロ > < 同 > < 回 > < 回 > < 回 > <

#### Brownian Net

Consider the paths  $(I_{z_1}, \ldots, I_{z_k}, r_{z'_1}, \ldots, r_{z'_{k'}})$  starting from the points  $(z_i)_{1 \le i \le k}$  and  $(z'_j)_{1 \le j \le k'}$  in  $\mathbb{R}^2$  that satisfy:

- $(l_{z_1}, \ldots, l_{z_k}, r_{z'_1}, \ldots, r_{z'_{k'}})$  evolve independently until they meet each other. The l-paths  $(l_{z_1}, \ldots, l_{z_k})$  coalesce when they meet and the same is true for the r-paths  $(r_{z'_1}, \ldots, r_{z'_{k'}})$ .
- Each pair of left-right paths ( $I_{z_i}, r_{z'_i}$ ) solves the following system of SDEs:

$$\begin{cases} dL_t = I_{\{L_t \neq R_t\}} dB_t^{l} + I_{\{L_t = R_t\}} dB_t^{s} - dt, \\ dR_t = I_{\{L_t \neq R_t\}} dB_t^{r} + I_{\{L_t = R_t\}} dB_t^{s} + dt, \end{cases}$$

where the l-path L and the r-path R have the restriction that  $L_t \leq R_t$  for all  $t \geq \inf\{u \geq \sigma_L \lor \sigma_R : L_u \leq R_u\}$ , with  $\sigma_L$  and  $\sigma_R$  being the starting times of L and R.

The pair of SDEs above has a unique solution and the above properties uniquely determine the joint law of  $(I_{z_1}, \ldots, I_{z_k}, r_{z'_1}, \ldots, r_{z'_{k'}})$ , called *left-right coalescing Brownian motions*.

▲ロト ▲御 ト ▲ 臣 ト ▲ 臣 ト の Q @

#### [Rongfeng Sun & Swart] Left-Right Brownian Web and it's dual

There exists an  $\mathcal{H}^2$ -valued random variable ( $\mathcal{W}^l, \mathcal{W}^r$ ), called the (standard) left-right Brownian Web, whose distribution is uniquely determined by the following properties:

- (i) For each deterministic  $z \in \mathbb{R}^2$ , W' and W' almost surely contain a single path each that start from point z;
- (ii) For any finite deterministic set of points z<sub>1</sub>,... z<sub>k</sub>, z'<sub>1</sub>,... z'<sub>k'</sub> ∈ ℝ<sup>2</sup>, the collection of paths (l<sub>z1</sub>,..., l<sub>zk</sub>, r<sub>z'1</sub>,..., r<sub>z'k'</sub>) is distributed as a family of left-right coalescing Brownian motions.
- (iii) For any deterministic countable dense sets  $\mathcal{D}', \mathcal{D}' \subset \mathbb{R}^2$ ,

$$\mathcal{W}' = \overline{\{I_z : z \in \mathcal{D}'\}} \text{ and } \mathcal{W}' = \overline{\{r_z : z \in \mathcal{D}'\}} \text{ a.s.}$$

Futhermore, almost surely there exists a dual left-right Brownian Web  $(\widehat{W}^l, \widehat{W}^r) \in \widehat{H}^2$ , such that  $(W^l, \widehat{W}^l)$  (resp.  $(W^r, \widehat{W}^r)$ ) is distributed as  $(W, \widehat{W})$  tilted with drift -1 (resp. +1).

## Brownian Net

Given a set of paths K, denote by  $\mathcal{H}_{cross}(K)$  the set of paths obtained by hopping a finite number of times among paths in K at crossing times. The Brownian Net is a  $(\mathcal{H}, \mathcal{B}_{\mathcal{H}})$ -valued random variable that can be constructed by setting  $\mathcal{N} = \overline{\mathcal{H}_{cross}(\mathcal{W}^{I} \cup \mathcal{W}^{r})}$ . It gives the hopping characterization of The Brownian Net.

#### Brownian Net

Given a set of paths K, denote by  $\mathcal{H}_{cross}(K)$  the set of paths obtained by hopping a finite number of times among paths in K at crossing times. The Brownian Net is a  $(\mathcal{H}, \mathcal{B}_{\mathcal{H}})$ -valued random variable that can be constructed by setting  $\mathcal{N} = \overline{\mathcal{H}_{cross}(\mathcal{W}^{l} \cup \mathcal{W}^{r})}$ . It gives the hopping characterization of The Brownian Net.

#### [Rongfeng Sun & Swart] Brownian Net - Wedge characterization

Let  $(\mathcal{W}^{l}, \mathcal{W}^{r}, \widehat{\mathcal{W}}^{l}, \widehat{\mathcal{W}}^{r})$  be the standard left-right Brownian Web and its dual. Then almost surely,

 $\mathcal{N} = \{\pi \in \Pi : \pi \text{ does not enter any wedge of } (\widehat{\mathcal{W}}^{l}, \widehat{\mathcal{W}}^{r}) \text{ from outside} \}$ 

is the standard Brownian Net associated with  $(\widehat{\mathcal{W}}^{l}, \widehat{\mathcal{W}}^{r})$ , i.e.,  $\mathcal{N} = \overline{\mathcal{H}_{cross}(\mathcal{W}^{l} \cup \mathcal{W}^{r})}$ .

Our main objective is to describe the asymptotic behavior of the diffusively rescaled DNB when  $\epsilon_n = bn^{-\alpha}$  for different values of  $\alpha > 0$ .

#### Theorem 1:

If  $\epsilon_n = \mathfrak{b} n^{-\alpha}$  for some  $\mathfrak{b} > 0$  and  $\alpha > 1$ , then  $\mathcal{X}^n_{\epsilon_n}$  converges in distribution in  $\mathcal{H}$  to the Brownian Web  $\mathcal{W}_{\lambda}$  when  $n \to \infty$ , where  $\lambda^2 = \lambda_p^2$  is the variance of an increment of a DNB path.

#### Theorem 2:

Let  $W_n^l$  (resp.  $W_n^r$ ) be the set of *l*-paths (resp. *r*-paths) of a diffusively rescaled DNB with parameter  $\epsilon_n = \mathfrak{b} n^{-1}$  for some  $\mathfrak{b} > 0$ . There exist  $\hat{W}_n^l$  and  $\hat{W}_n^r$  dual processes of  $W_n^l$  and  $W_n^r$  respectively such that

$$(W_n^l, W_n^r, \hat{W}_n^l, \hat{W}_n^r) \Longrightarrow (\mathcal{W}_{\lambda, b_p}^l, \mathcal{W}_{\lambda, b_p}^r, \widehat{\mathcal{W}}_{\lambda, b_p}^l, \widehat{\mathcal{W}}_{\lambda, b_p}^r) \quad as \quad n \to \infty,$$

where  $b_p = \frac{b(1-p)}{(2-p)^2}$ .

< ロ > < 同 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

#### Drainage Network with Branching - Main results

#### Theorem 3:

If we have  $\mathcal{X}_{\epsilon_n}^n$  the diffusively rescaled Drainage Network with branching parameter  $\epsilon_n = \mathfrak{b} n^{-1}$  for  $\mathfrak{b} > 0$ , then  $\mathcal{X}_{\epsilon_n}^n$  is tight and any subsequential limit contains the Brownian Net  $\mathcal{N}_{b_{p,\lambda}}$  with  $b_p = \frac{\mathfrak{b}(1-p)}{(2-p)^2}$ .

We conjecture that  $\mathcal{X}_{\epsilon_n}^n$  converges to  $\mathcal{N}_{b_p,\lambda}$ 

## Two key ingredients of the proofs

- Control on the probability of "long jumps": For any fixed s > 0 and n ∈ N, the probability that an specific path π from the DNB will make at least one jump of size greater than g ≥ 1 in a time window of size sn<sup>2</sup> is bounded from above by 2sn<sup>2</sup>e<sup>-c(g-1)</sup>, for some c = c<sub>p</sub> > 0.
- Estimates for coalescence times: Let  $\tau_k$  denote the time until coalescence between two l-paths (or two r-paths) that start within distance k from each other. There exists a constant  $C_0 > 0$  such that for every t > 0 and  $k \in \mathbb{N}$  we have:

$$P( au_k > t) \leq rac{C_0 k}{\sqrt{t}}.$$

Consider a sequence of  $(\mathcal{H}, \mathcal{B}_{\mathcal{H}})$ -valued random variables  $(\mathcal{Z}_n)_{n \in \mathbb{N}}$ . If  $(\mathcal{Z}_n)_{n \in \mathbb{N}}$  satisfies the following four conditions, then it converges to a Brownian Web.

**(T)**: The law of  $(\mathcal{Z}_n)_{n \in \mathbb{N}}$  is tight.

(I): There exists  $\pi_{n,z} \in \mathcal{Z}_n$  for each  $z \in \mathbb{R}^2$ , such that for any deterministic  $z_1, \ldots, z_k \in \mathbb{R}^2$ ,  $(\pi_{n,z_i})_{1 \le i \le k}$  converge in distribution to coalescing Brownian motions starting at  $(z_i)_{1 \le i \le k}$ .

**(B1\*)**: For any  $\mathcal{Z}$  a subsequential weak limit of  $\mathcal{Z}_n$ , we have that for all t > 0,

$$\limsup_{\delta \downarrow 0} \sup_{a,t_0 \in \mathbb{R}} P[\eta_{\mathcal{Z}}(t_0,t;a,a+\delta) \geq 2] = 0$$

where  $\eta_{\mathcal{X}}(t_0, t; a, b) = |\{\pi(t_0 + t) : \pi \in \mathcal{X}, \pi(t_0) \in [a, b]\}|, t_0 \in \mathbb{R}, t > 0, a < b$ , which counts the number of distinct paths in  $\mathcal{X}$  at time  $t_0 + t$ , among all paths that start from interval [a,b] at time  $t_0$ .

**(B2\*)**: For any  $\mathcal{Z}$  a subsequential weak limit of  $\mathcal{Z}_n$ , we have that for all t > 0

$$\limsup_{\delta \downarrow 0} \frac{1}{\delta} \sup_{a,t_0 \in \mathbb{R}} P[\eta_{\mathcal{Z}}(t_0, t; a, a + \delta) \ge 3] = 0.$$

(日)

We conjecture that the DNB with branching parameter  $\epsilon_n = bn^{-1}$  converges to the Brownian Net under diffusive scaling. But to prove that, still remains to verify that the Brownian Net is an upper bound to any subsequential limit that we obtain in Theorem 3, which can be achieved by proving that condition  $(U''_N)$  holds.

So, we need to verify that for any subsequential weak limit  $(X, W', W^r, \widehat{W}^l, \widehat{W}^r)$ of  $(X_n, W_n^l, W_n^r, \widehat{W}_n^l, \widehat{W}_n^r)$  and for any deterministic countable dense set  $D \subset \mathbb{R}^2$ , a.s. paths in X do not enter any wedge of  $(\widehat{W}^l(D), \widehat{W}^r(D))$  from outside.
